
(a) For every described species, the time needed to detect a 30% decline per decade from its observed GBIF record rate (2015–2024), using the curves in Fig. 2a. Invertebrate and small marine groups ordered by typical body mass; mammals and birds by body-mass class. (b) Ratio of DNA-derived to human-observation records against body mass (abundance cancels in the ratio); slopes with 95% intervals propagating census and residual uncertainty.
